总体的思路:

- 1.把原先写死的路由放到数据库
- 2.通过后台方法包括递归等返回对应的基本上和之前写死一样的数据和结构(可能会有细微的差别)
- 3.前端获取通过改造router下面的index.js文件,获取后端路由,并且拼接到现在的路由上,核心的代码:

```
const formatRoutes = (data) =>{
const res = [];
data.forEach(item => {
const tmp = {
...item
};
if (tmp.Children) {
tmp.children = formatRoutes(tmp.Children);
}
let route = {
path: tmp.Path,
//这个是一个关键点, 因为webpack编译的时候, 动态载入的路由通过import的方式会不能识别, 所以一定要用

// 这种写法 resolve => require(['@/' + tmp.Component.replace('@/', '').replace('.vue', '') + '.vue'], resolve)
```

```
component: tmp.Component === 'Layout' ? Layout : resolve => require(['@/' +
   tmp.Component.replace('@/', '').replace('.vue', '') + '.vue'], resolve),
        name: tmp.Name,
        meta: {
          title: tmp.Meta_Title,
          icon: tmp.Meta Icon
        },
        children: tmp.children || [],
        hidden: tmp.Hidden
      };
      // 如果tmp.ParentId为null,添加redirect属性
      if (tmp.ParentId === null) {
        route.redirect = tmp.Path;
      res.push(route);
    });
    return res;
32 };
```

4.测试,测试是软件开发永恒的话题,也是最基本上的构成,如果没有测试,软件就是不可靠的,是不 能称之为真正的软件的

重要关键点如下:

1.vue里面登录会内置角色,我们的角色一定要是固定的,然后登录系统的角色来通过其他的字段来赋值即可

```
1 {
2    url: '/vue-element-admin/user/info\.*',
3    type: 'get',
4    response: config => {
5       const { token } = config.query
6       const userinfo = JSON.parse(token)
7       console.log('userinfo', userinfo)
8       const info = users[userinfo.role + userinfo.EnterprisesType]
9
```

```
console.log('政府主管部门', info, users, userinfo)
 if (userinfo.role === 'ZG') {
   if (!info.roles.includes(userinfo.usertype)) {
     info.roles.unshift(userinfo.usertype);
   }
 }
 if (!info) {
   return {
     code: 50008,
     message: 'Login failed, unable to get user details.'
   }
 } else {
   info.userid = userinfo.userid
   info.fullname = userinfo.fullname
   info.unitcode = userinfo.unitcode
   info.usertype = userinfo.usertype
   info.avatar = userinfo?.avatar
 return {
   code: 20000,
   data: info
}
```

2.后端的主要代码如下

```
return Task.FromResult(ret);
            }
            catch (Exception ex)
            {
                Console.WriteLine(ex.Message);
                return default:
            }
        }
        public Task<MenuDto> QueryRolePermission(string role, string userName = "")
        {
            try
            {
                var rep = this.commonRepositoryFactory.BaseRepository();
                var all = rep.FindList<MenuModel>().Result.ToList();
                var menus = all.Where(o => o.RoleCode.Split(',')
                           .Select(x => x.Trim().ToUpper())
                          .Contains(role.Trim().ToUpper()))
                .ToList();
                var treeList = TransformToTreeList(menus);
                var ret = new MenuDto { treeList = treeList, ids = menus.Select(x => x.
Id).ToList() };
                return Task.FromResult(ret);
            }catch(Exception ex)
            {
                Console.WriteLine(ex.Message);
                return default;
            }
        }
        private List<MenuModel> TransformToTreeList(List<MenuModel> menus, string paren
tId = null)
```

```
{
            var treeList = new List<MenuModel>();
            foreach (var menu in menus.Where(m => m.ParentId == parentId).OrderBy(m =>
m.Sort))
            {
                menu.Children = TransformToTreeList(menus, menu.Id);
                treeList.Add(menu);
            return treeList;
        }
        public async Task<bool> SaveRolePermission(string role, string permissionIds)
        {
            try
            {
                var rep = this.commonRepositoryFactory.BaseRepository();
                //var allValidRoleCodes = (await rep.FindList<RoleModel>
                var menus = (await rep.FindList<MenuModel>()).ToList();
                string[] permissionIdArray = permissionIds.Split(",");
                foreach (var menu in menus)
                {
                    string[] roles = (menu.RoleCode ?? "").Split(new[] { ',' }, StringS
plitOptions.RemoveEmptyEntries);
                    bool containsRole = roles.Contains(role);
                    // 判断是否在权限ID列表中
                    bool inPermissionList = permissionIdArray.Contains(menu.Id);
```

```
if (inPermissionList)
            {
                if (!containsRole)
                {
                    roles = roles.Append(role).ToArray();
                }
            }
            else
                if (containsRole)
                {
                    roles = roles.Where(r => r != role).ToArray();
                }
            }
            menu.RoleCode = String.Join(",", roles);
        await rep.UpdateEx(menus);
        return true;
    }
    catch (Exception ex)
        Console.WriteLine(ex.Message);
        return false;
    }
}
```
